SPRUCE BUDWORM POPULATIONS IN NOVA SCOTIA

I. INTRODUCTION

There are three major surveys of spruce budworm (Choristoneura fumiferana (Clemens, 1865)) in Nova Scotia. These surveys are both descriptive and predictive in nature. The three surveys are (1) aerial defoliation survey, (2) moth flight survey and (3) survey of overwintering larvae (L-2 survey). In 1984 the L-2 survey data were used in conjunction with those from the spruce budworm egg-mass survey. In 1985 the L-2 survey has replaced the egg-mass survey.

The spruce budworm egg-mass survey of 1984 detected a concentration and intensification of the spruce budworm infestation in Central Cumberland County and along the Northumberland Coast. Defoliation was noted in these areas during 1985.

II. AERIAL DEFOLIATION SURVEY

The aerial defoliation survey is conducted by the Forest Insect and Disease Survey Group of the Maritime Forest Research Centre with assistance from the Department of Lands and Forests.

In 1985 inclement weather hampered the aerial defoliation survey. In many areas heavy rain washed the discoloured needles from the trees prior to the survey. This year 26 394 ha of light, 32 114 ha of moderate and 6 644 ha of

severe defoliation, and 280 103 ha of severe with moderate patches were noted (Table 1, Figure 1) as compared to 26 355 ha of light, 32 777 ha of moderate, and 25 939 ha of severe defoliation in 1984 (Table 2, Figure 2).

Table 1. Areas of spruce budworm defoliation in Nova Scotia by County in 1985.

County	Light	Moderate	Severe with Moderate Patches	Severe	Total

Pendrel, Smith and Magasi, 1985

III. MOTH FLIGHT SURVEY

The Department in conjunction with Agriculture Canada, Environment Canada, Ministry of State-Forestry, Transport Canada, Nova Scotia Agriculture and Marketing operate a system of light traps to sample photopositive night flying insect species. Failure of the Department's light traps hindered the efforts of this year's survey. However, no major adult migrations of spruce budworm adults were observed this year.

IV. L-2 SURVEY

The objective of the L-2 survey is predictive in nature. The data from this survey are used to forecast expected population densities and define areas of risk. The spruce budworm larvae migrate after eclosion and before hibernation. For this reason the L-2 data are better estimators of the current population than are those data of the egg-mass survey. This year the L-2 survey has replaced the egg-mass survey for Nova Scotia.

A. Methods

1. Field

There were 420 L-2 sample points within the Province. Field samples from 362 locations were collected by Lands and Forests personnel (331), Bwoater-Mersey personnel (31) (Table 3).

Table 3. Number of sample locations for L-2 Survey, Nova Scotia, 1985.

<u>Agency</u>	<u>Sample location</u>			
	<u>Assigned</u>	<u>Collected</u>	<u>Uncollected</u>	<u>Late</u>
Lands & Forests	369	331	25	15
Bowater-Mersey	51	31	5	15
Total	420	362	30	30

2. Laboratory

The Insectary at Debert has been modified to process L-2 samples. Hibernating coiferophagus larvae are removed from foliage by treating softwood foliage with a hot (66°C) solution (1.5 percent volume) of sodium hydroxide. Larvae were separated from plant debris by differential wetting technique using hexane. Larvae were enumerated on gridded filterpapers under a Wild-Leitz M5 stereo microscope (Miller et al 1971, Miller and Kettela 1982, Dorais and Kettela 1982, and Trail 1984).

3. Results

In the Maritimes the population levels are expressed as number of larvae per 45 cm branch tip (Table 4).

Table 1. Population assessment and infestation levels of second instar spruce budworm larvae.

Regions	Population Assessment Larvae/branch	Larvae/10 m ²	Infestation Level
Maritimes	1-6	-	Low
	7-20	-	Medium
	21-40	-	High
	41+	-	Extreme
Ontario	1-25	-	Low
	26-65	-	Medium
	66	-	High
Maine	-	0	None
Quebec	-	1-100	Low
Newfoundland	-	101-300	Medium
	-	301-650	High
	-	651	Extreme

(Dorais and Kettela 1982)

In general the current spruce budworm infestation remains intensified and concentrated in Central Cumberland County and along the Northumberland Coast. Sample areas with similar population densities were mapped to produce the G-2 map (Figure 3). The egg-mass map of 1984 is included for general comparison (Figure 2). L-2 data for 1984 and 1985 are presented in Appendices 1 and 2 respectively. The mean population densities of the 1985 data are presented in Appendix 3.

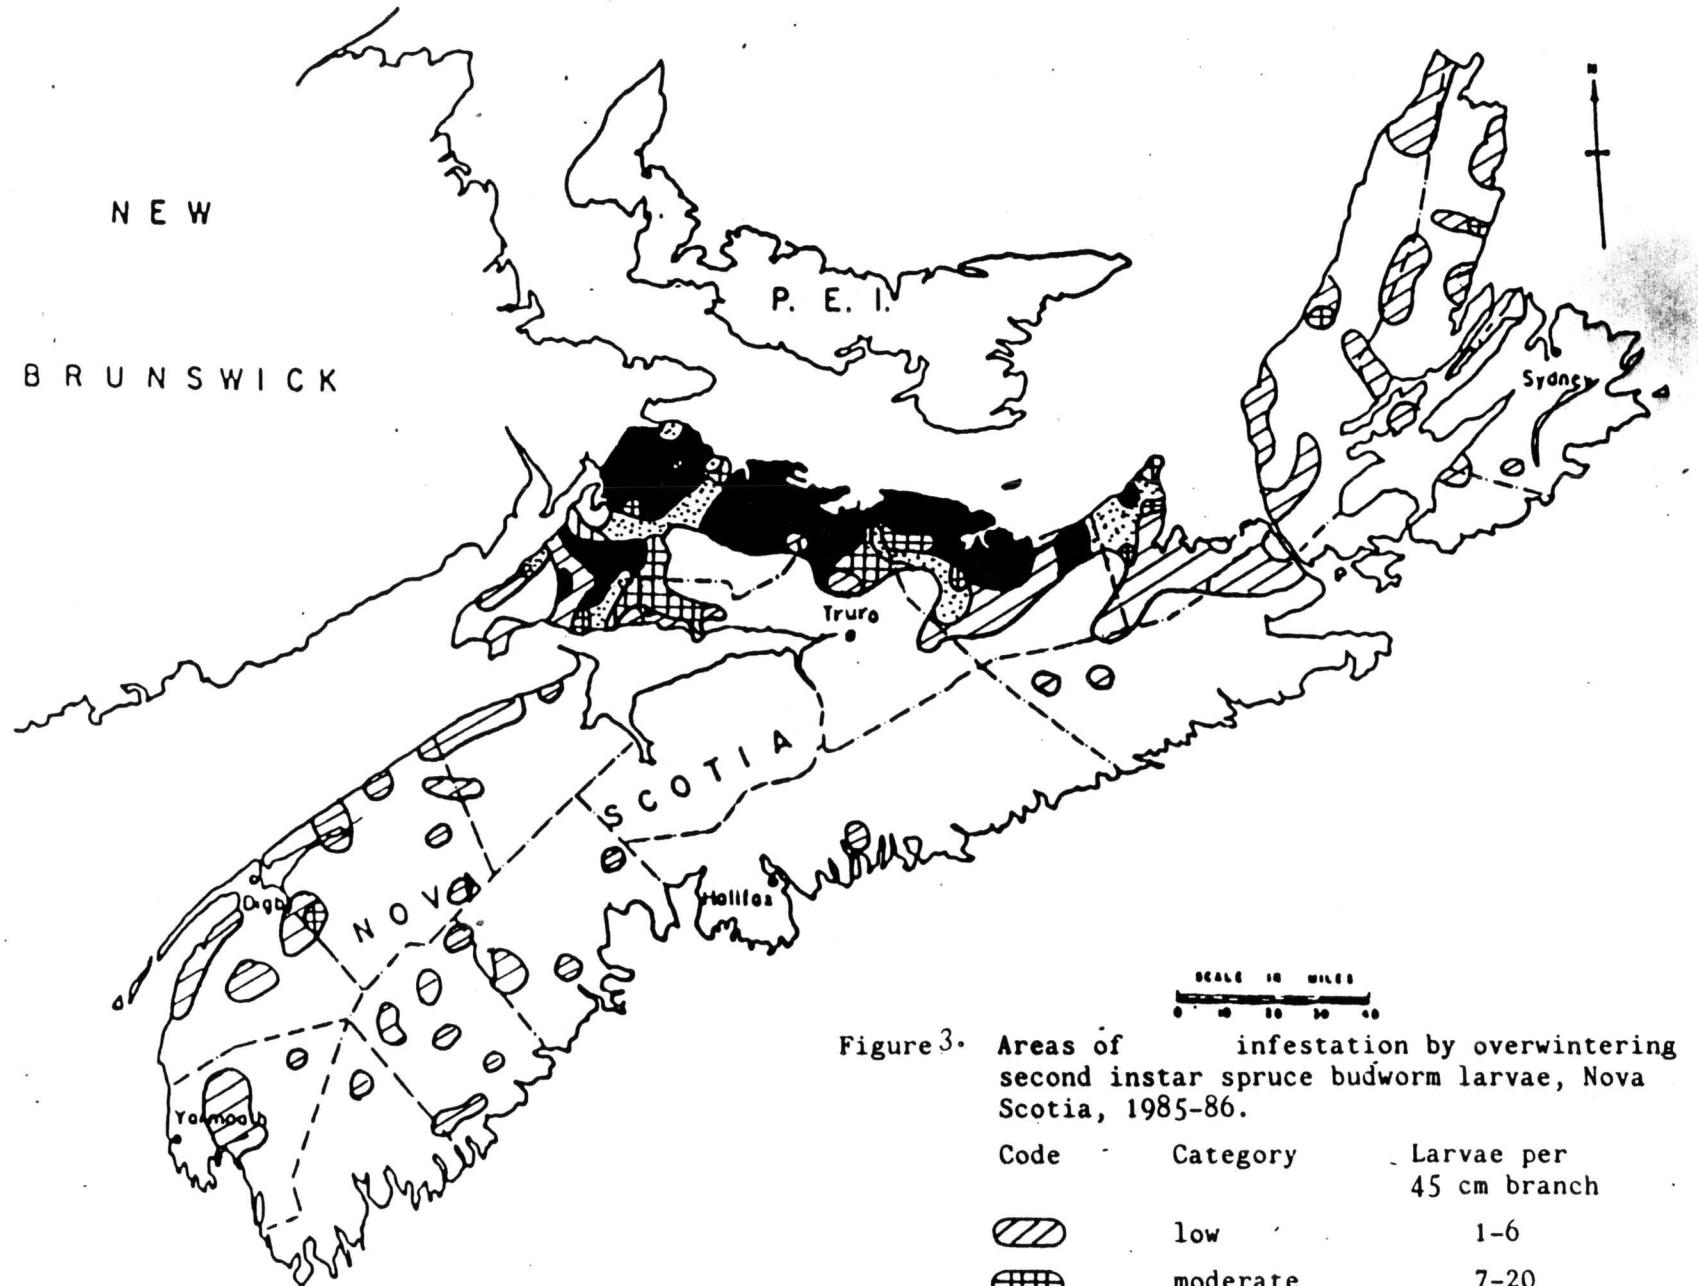

Figure 3. Areas of infestation by overwintering second instar spruce budworm larvae, Nova Scotia, 1985-86.

Code	Category	Larvae per 45 cm branch
	low	1-6
	moderate	7-20
	high	21-40
	extreme	41+

A. Cape Breton

There has been an increase in the frequency of low populations on the Cape Breton Highlands (Figures 3 and 4) as compared to those areas in 1984. This year moderate populations were noted at Little River in Victoria County and again as in 1984 at Southwest Margaree in Inverness County. Low populations have noted in the McEvays Barren area, Mabou and Creignish Hills area.

B. Mainland Nova Scotia

(i) Southern Counties

There has been a shift in populations. The areas of moderate populations in 1984 have collapsed in particular those at the Head of St. Margaret's Bay. There is, however, an area of moderate populations near Digby. Low populations have been noted in Kings, Annapolis, Digby, Yarmouth, Shelburne, Queens, Lunenburg and Halifax counties. Summaries of the frequencies of occurrence of L-2 category classes for each county are presented in Appendix 4.

(ii) Northern Counties

The spruce budworm infestation is continuing to persist in Cumberland County along the Northumberland Coast, and the Cape George area of Antigonish County. There is a general decline in the intensity of the number of second instar larvae

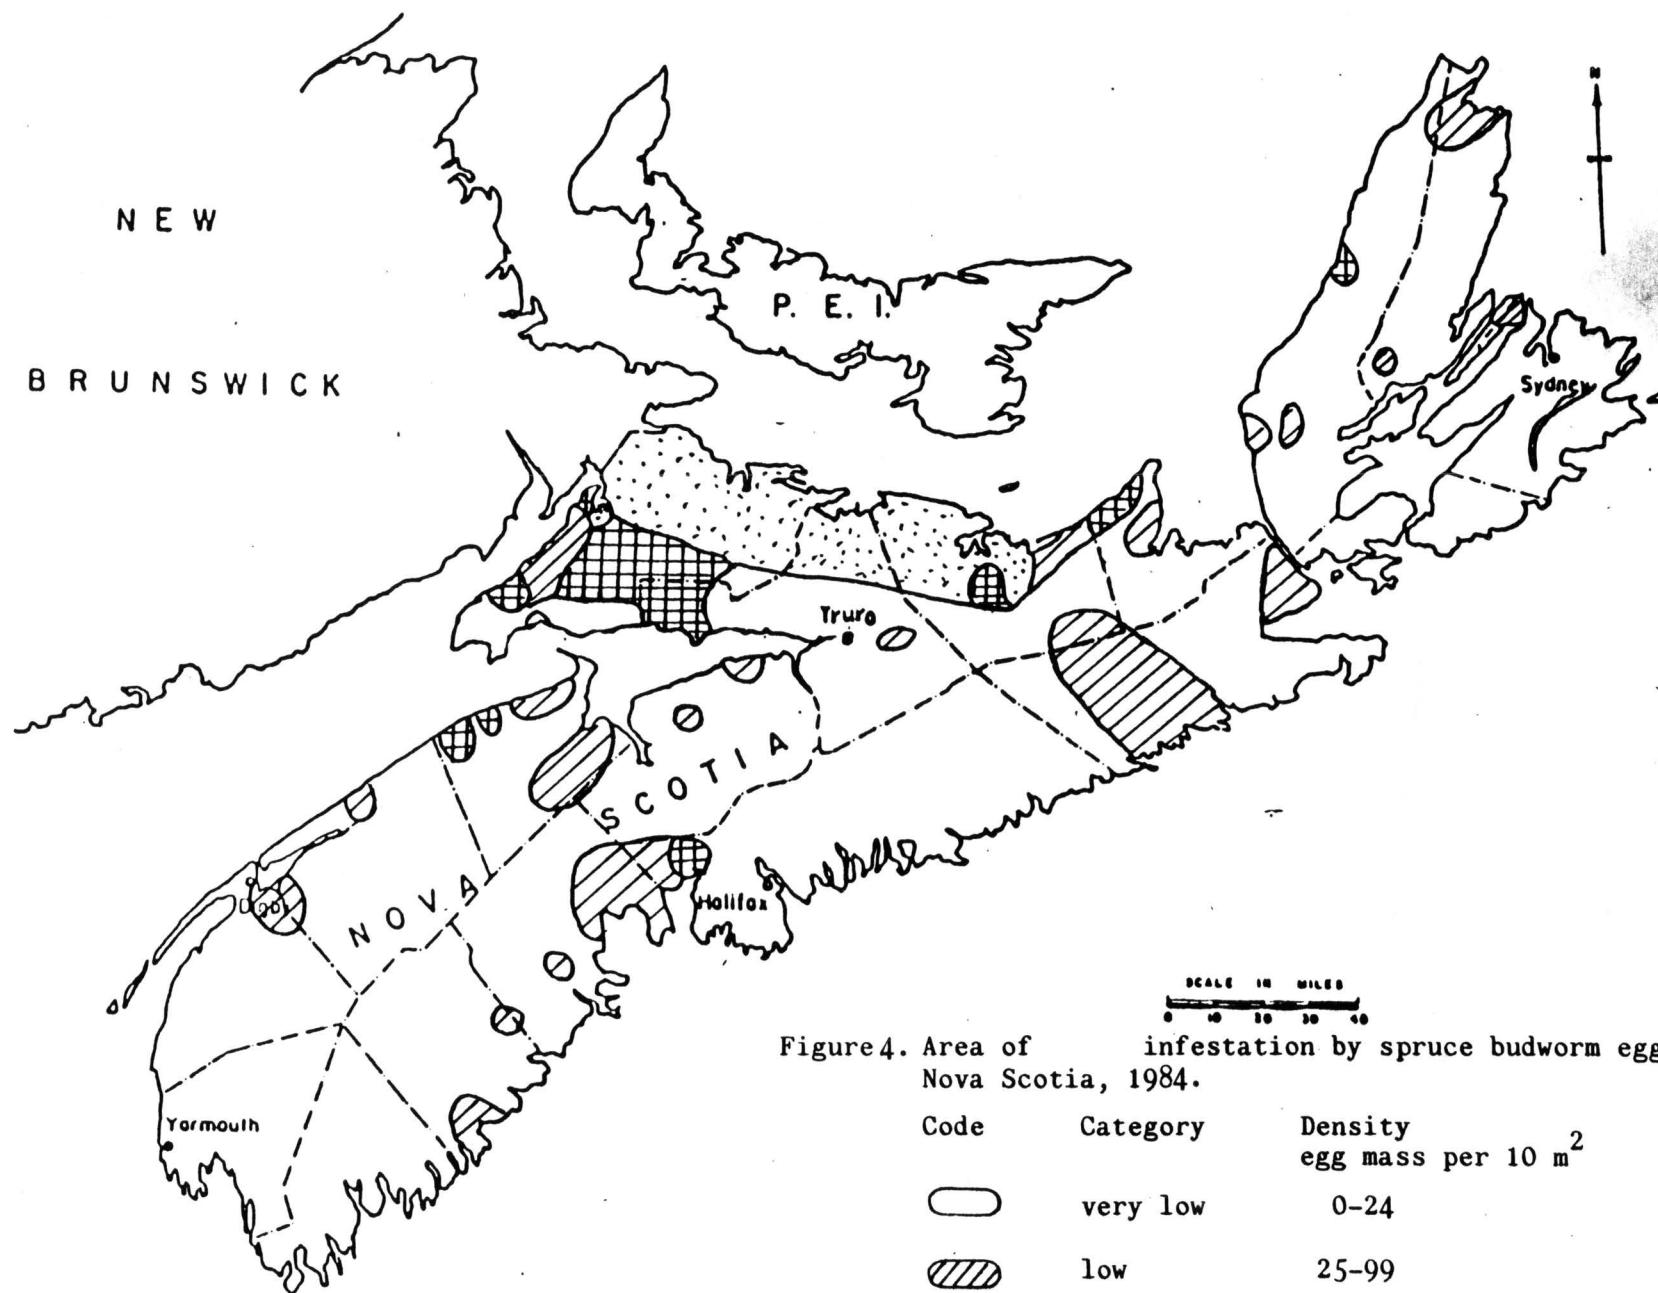

Figure 4. Area of infestation by spruce budworm egg-masses Nova Scotia, 1984.

Code	Category	Density egg mass per 10 m ²
○	very low	0-24
▨	low	25-99
▨▨	moderate	100-239
▨▨▨	high	240+

per 45 cm branch tip of about 56 percent (Tables 3 to 6). The magnitude of this reduction should be tempered with caution as the data for the 1984 L-2 survey are restricted to the infested zone whereas the data for the 1985 L-2 survey include samples from outside the infestation. For Antigonish County the mean number of larvae per 45 cm branch is 24.8 ± 20.0 . Thus the reduction in population in the infested area is 43.8 percent as compared to a county reduction of 64.0 percent (Tables 4,5,6 and 7). The populations of spruce budworm continue to pose a serious threat to our softwood forests in Central Cumberland County, on the Maritime Plain along the Northumberland Coast and the Cape George Peninsula of Antigonish County. Noticable defoliation can be expected to occur in these areas. Populations in the rest of the Province should be carefully monitored next year. Care must be taken to monitor possible range overlaps and combined defoliation of spruce budworm with spruce cone worm (Dioryctria reniculelloides Mut. & Mun.) in Colchester County, spruce budmoth Zeiraphera canadensis Mut. & Free. in Antigonish County. White marked tussock moth (Orgyia leucostigma J.E. Smith) in Antigonish, Guysborough and Halifax counties and hemlock looper (Lambdina fiscellaria fiscellaria (Guen) in Cumberland and Yarmouth counties.

% Change Infestation $(100 - ((\hat{x}_{85} \div \bar{x}_{84}) \cdot 100)) = 24.6$

V. SUMMARY

The spruce budworm infestations are persisting, still at high levels, in the Province principally in Cumberland County and along the Northumberland Coast. Noticeable defoliation can be expected through this infested area in 1986. Low populations have been noted on the Cape Breton Highlands and in the Southern counties, trace to light defoliation may occur in these areas in 1986.
